

### What is Scheduling?

- On a multi-programmed system
  - We may have more than one Ready process
- On a batch system
  - We may have many jobs waiting to be run
- On a multi-user system
  - · We may have many users concurrently using the system
- The **scheduler** decides who to run next.
  - The process of choosing is called scheduling.

### Is scheduling important?

- · It is not in certain scenarios
  - If you have no choice
    - · Early systems
      - Úsuálly batching
      - Scheduling algorithm simple
      - » Run next on tape or next on punch tape
  - Only one thing to run
    - Simple PCs
      - Only ran a word processor, etc....
    - · Simple Embedded Systems
      - TV remote control, washing machine, etc....

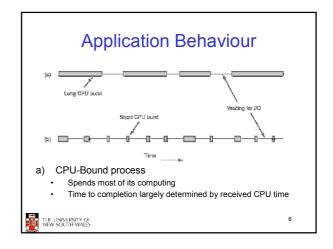

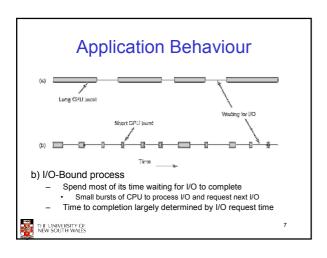

### Is scheduling important?

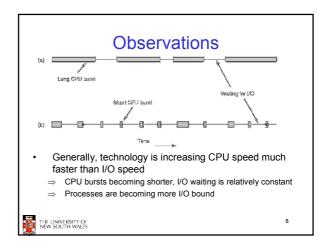

- It is in most realistic scenarios
  - Multitasking/Multi-user System
    - Example
      - Email daemon takes 2 seconds to process an email
        User clicks button on application.
    - Scenario 1
      - Run daemon, then application
    - » System appears really sluggish to the user
    - Scenario 2
      - Run application, then daemon
        - » Application appears really responsive, small email delay is unnoticed
- Scheduling decisions can have a dramatic effect on the perceived performance of the system
  - Can also affect correctness of a system with deadlines

### Categories of Scheduling Algorithms

- The choice of scheduling algorithm depends on the goals of the application (or the operating system)
  - No one algorithm suits all environments
- We can roughly categorise scheduling algorithms as follows
  - Batch Systems
    - No users directly waiting, can optimise for overall machine performance
  - Interactive Systems
    - Users directly waiting for their results, can optimise for users perceived performance
  - Realtime Systems
    - Jobs have deadlines, must schedule such that all jobs (mostly) meet their deadlines

13

### Goals of Scheduling Algorithms

- · All Algorithms
  - Fairness
    - · Give each process a fair share of the CPU
  - Policy Enforcement
    - What ever policy chosen, the scheduler should ensure it is carried out
  - Balance/Efficiency
    - · Try to keep all parts of the system busy

14

### Goals of Scheduling Algorithms

- · Batch Algorithms
  - Maximise throughput
    - Throughput is measured in jobs per hour (or similar)
  - Minimise turn-around time
    - Turn-around time (T<sub>r</sub>)
      - difference between time of completion and time of submission
    - Or waiting time  $(T_w)$  + execution time  $(T_e)$
  - Maximise CPU utilisation
    - Keep the CPU busy
    - · Not as good a metric as overall throughput

15

### Goals of Scheduling Algorithms

- · Interactive Algorithms
  - Minimise response time
    - Response time is the time difference between issuing a command and getting the result
      - E.g selecting a menu, and getting the result of that selection
    - Response time is important to the user's perception of the performance of the system.
  - Provide Proportionality
    - Proportionality is the user expectation that short jobs will have a short response time, and long jobs can have a long response time.
    - · Generally, favour short jobs

16

### Goals of Scheduling Algorithms

- · Real-time Algorithms
  - Must meet deadlines
    - Each job/task has a deadline.
    - A missed deadline can result in data loss or catastrophic failure
      - Aircraft control system missed deadline to apply brakes
  - Provide Predictability
    - For some apps, an occasional missed deadline is okay
      - E.g. DVD decoder
    - Predictable behaviour allows smooth DVD decoding with only rare skips

17

### Scheduling Algorithms

**Batch Systems** 

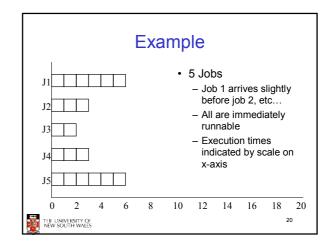

18

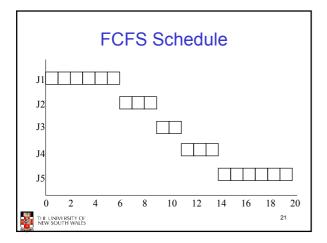

### First-Come First-Served (FCFS)

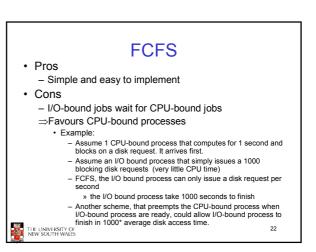

- Algorithm
  - Each job is placed in single queue, the first job in the queue is selected, and allowed to run as long as it wants.
  - If the job blocks, the next job in the queue is selected to run
  - When a blocked jobs becomes ready, it is placed at the end of the queue

19

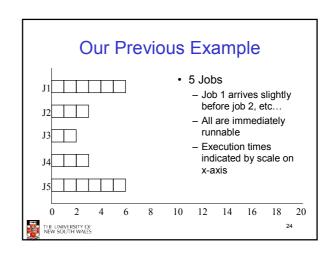

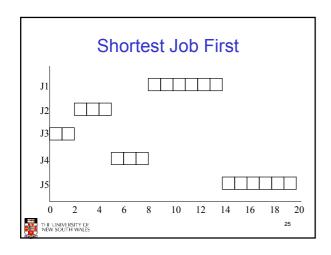

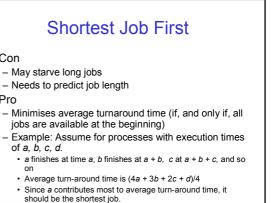

### **Shortest Job First**

- If we know (or can estimate) the execution time a priori, we choose the shortest job firet
- · Another non-preemptive policy

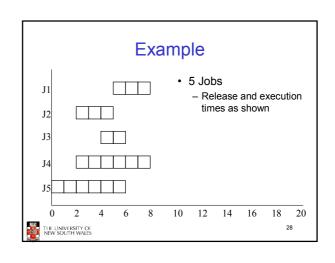

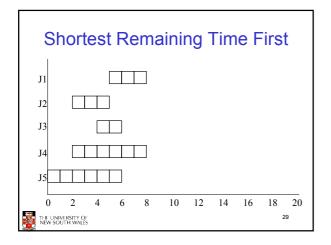

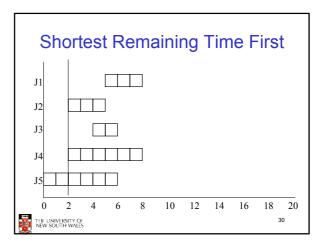

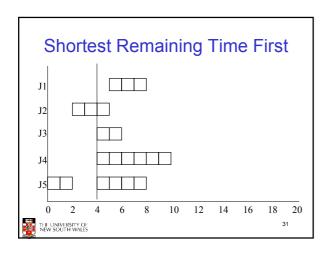

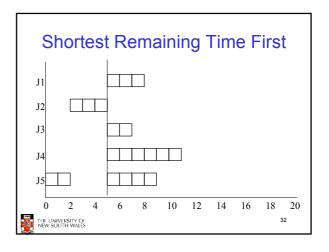

# Shortest Remaining Time First • A preemptive version of shortest job first • When ever a new jobs arrive, choose the one with the shortest remaining time first – New short jobs get good service

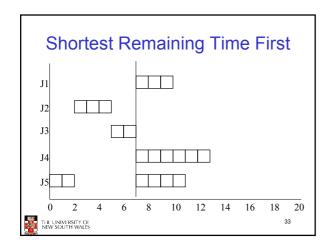

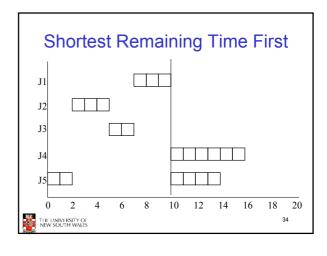

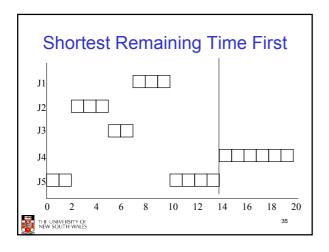

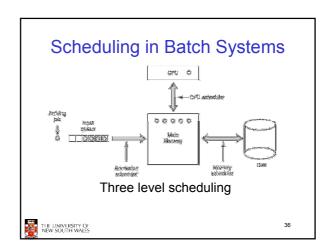

# Three Level Scheduling

- · Admission Scheduler
  - Also called *long-term* scheduler
  - Determines when jobs are admitted into the system for processing
  - Controls degree of multiprogramming
  - More processes ⇒ less CPU available per process

37

# Three Level Scheduling

- · CPU scheduler
  - Also called short-term scheduler
  - Invoked when ever a process blocks or is released, clock interrupts (if preemptive scheduling), I/O interrupts.
  - Usually, this scheduler is what we are referring to if we talk about a scheduler.

38

# Three Level Scheduling

- · Memory Scheduler
  - Also called medium-term scheduler
  - Adjusts the degree of multiprogramming via suspending processes and swapping them out

39
