Anticipatory Disk Scheduling

Sitaram Iyer Peter Druschel

Rice University

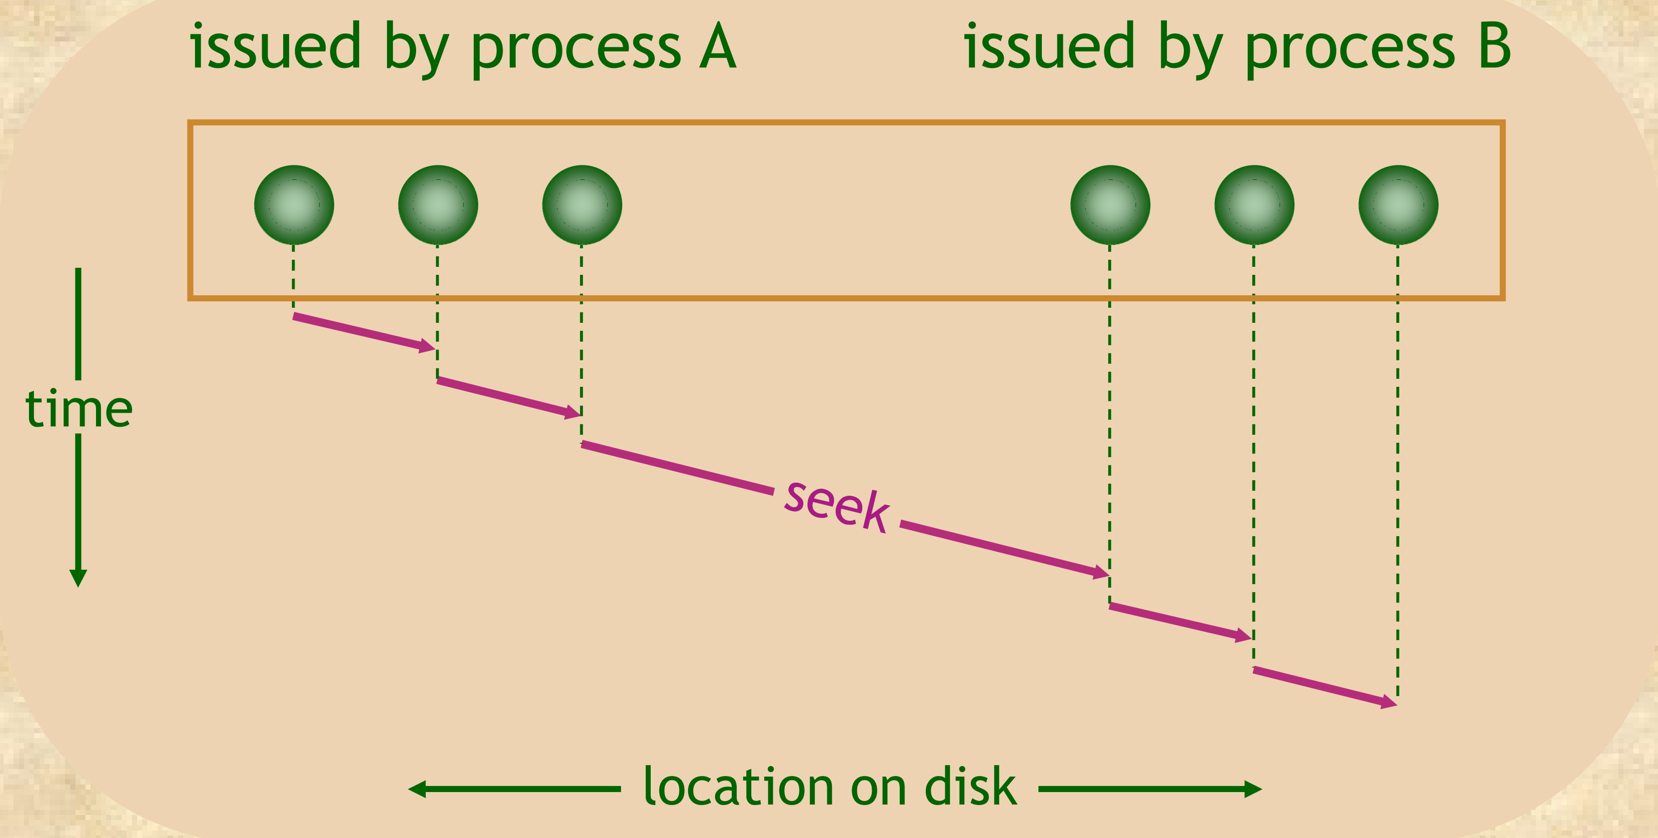
Disk schedulers

Reorder available disk requests for

- performance by seek optimization,
- proportional resource allocation, etc.

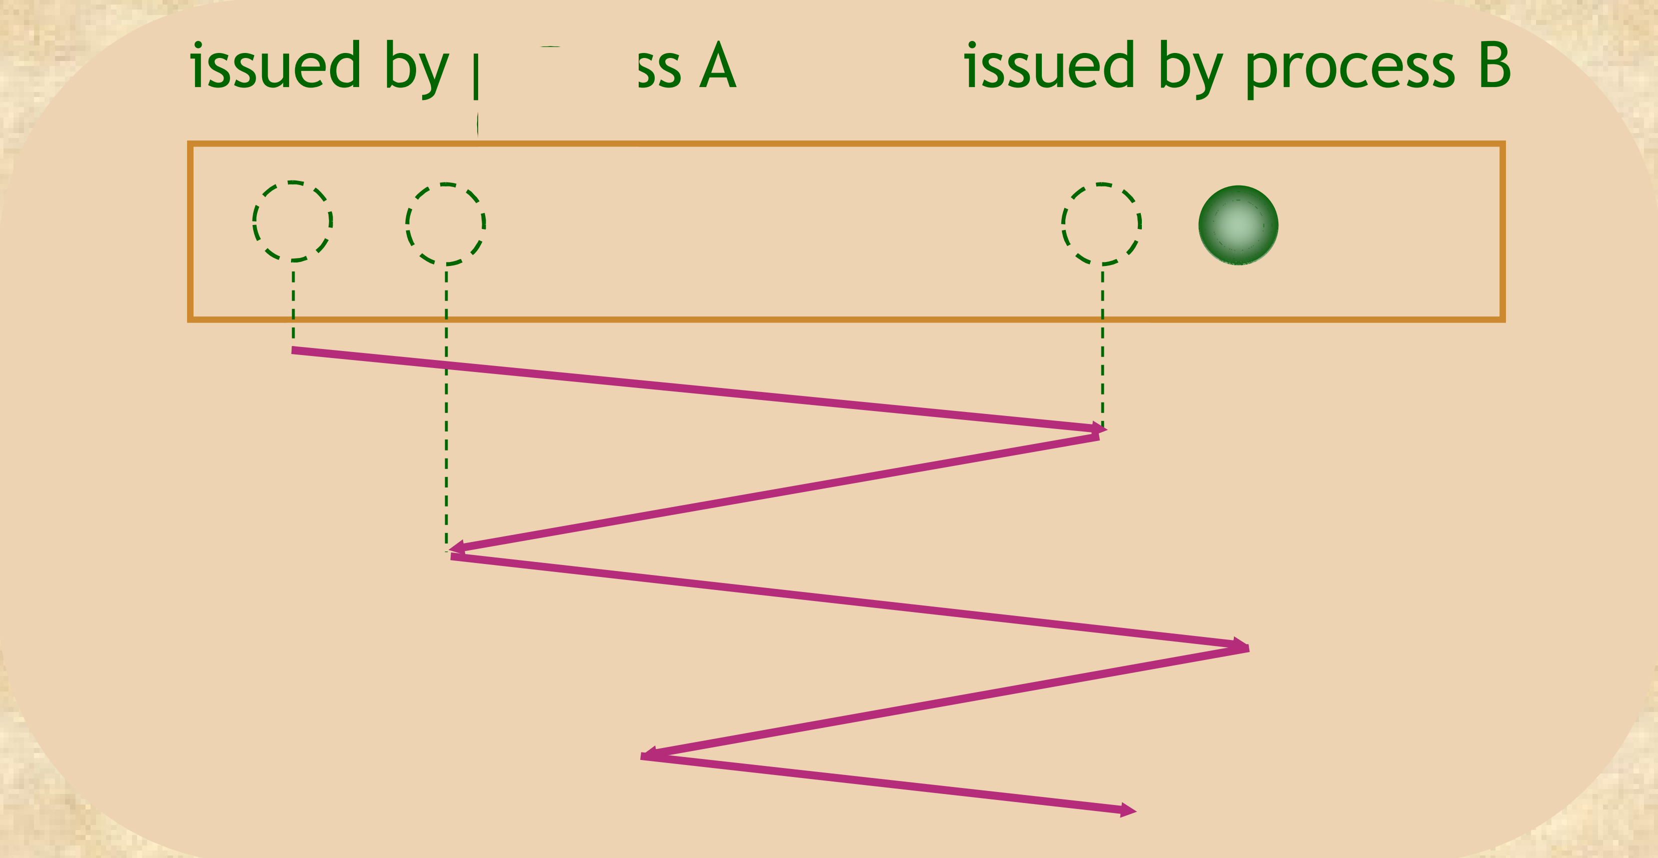
Any policy needs multiple outstanding requests to make good decisions!

With enough requests…



E.g., Throughput = 21 MB/s (IBM Deskstar disk)

With synchronous I/O…



E.g., Throughput = 5 MB/s

Deceptive idleness

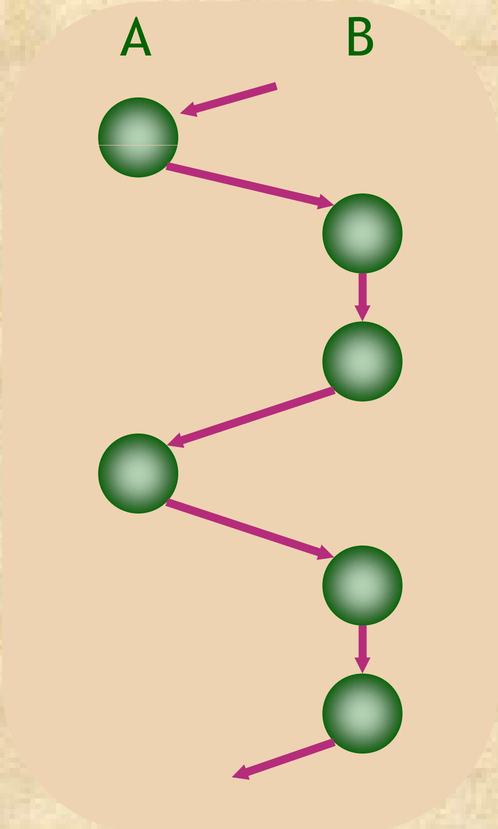
Process A is about to issue next request.

but

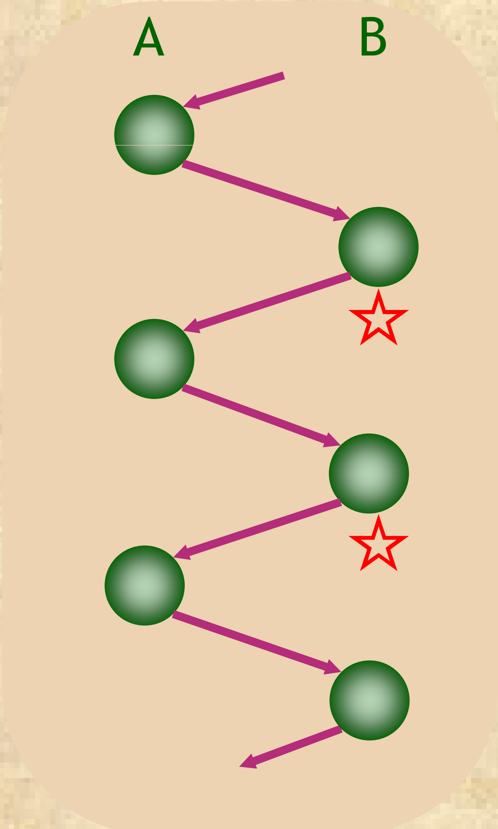
Scheduler hastily assumes that process A has no further requests!

Proportional scheduler

Allocate disk service in say 1:2 ratio:



Deceptive idleness causes 1:1 allocation:



Anticipatory scheduling

Key idea: Sometimes wait for process whose request was last serviced.

Keeps disk idle for short intervals.

But with informed decisions, this:

- Improves throughput
- Achieves desired proportions

Cost-benefit analysis

Balance expected benefits of waiting against cost of keeping disk idle.

Tradeoffs sensitive to scheduling policy

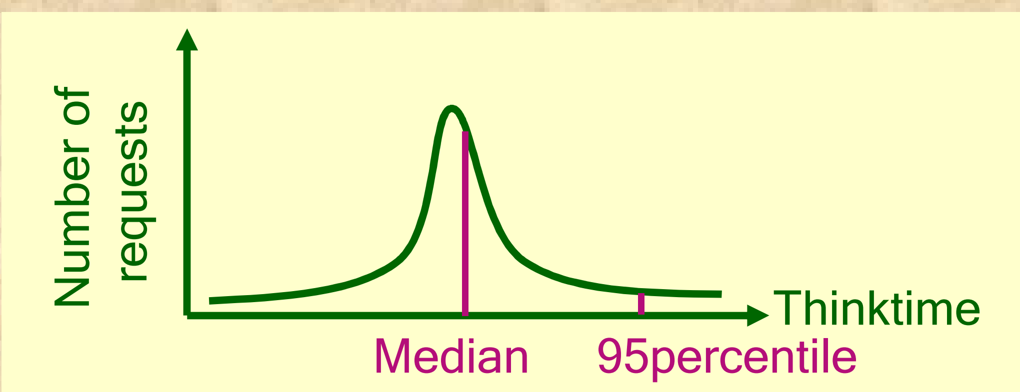
e.g., 1. seek optimizing scheduler

2. proportional scheduler

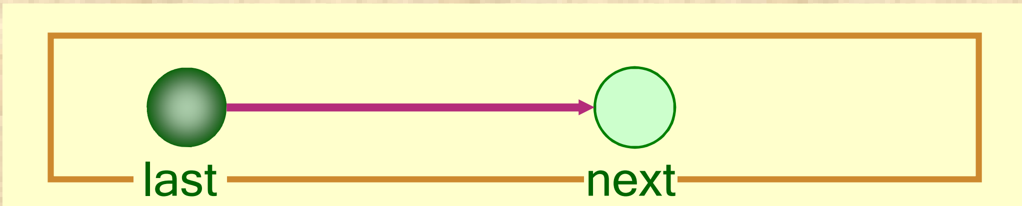
Statistics

For each process, measure:

1. Expected median and 95percentile thinktime



2. Expected positioning time



Cost-benefit analysis for seek optimizing scheduler

best := best available request chosen by scheduler

next := expected forthcoming request from process whose request was last serviced

Benefit =

best.positioning_time — next.positioning_time

Cost = next.median_thinktime

Waiting_duration =

(Benefit > Cost) ? next.95percentile_thinktime : 0

Proportional scheduler

Costs and benefits are different.

e.g., proportional scheduler:

Wait for process whose request was last serviced,
1. if it has received less than its allocation, and
2. if it has thinktime below a threshold (e.g., 3ms)

Waiting_duration = next.95percentile_thinktime

Prefetch

Overlaps computation with I/O.

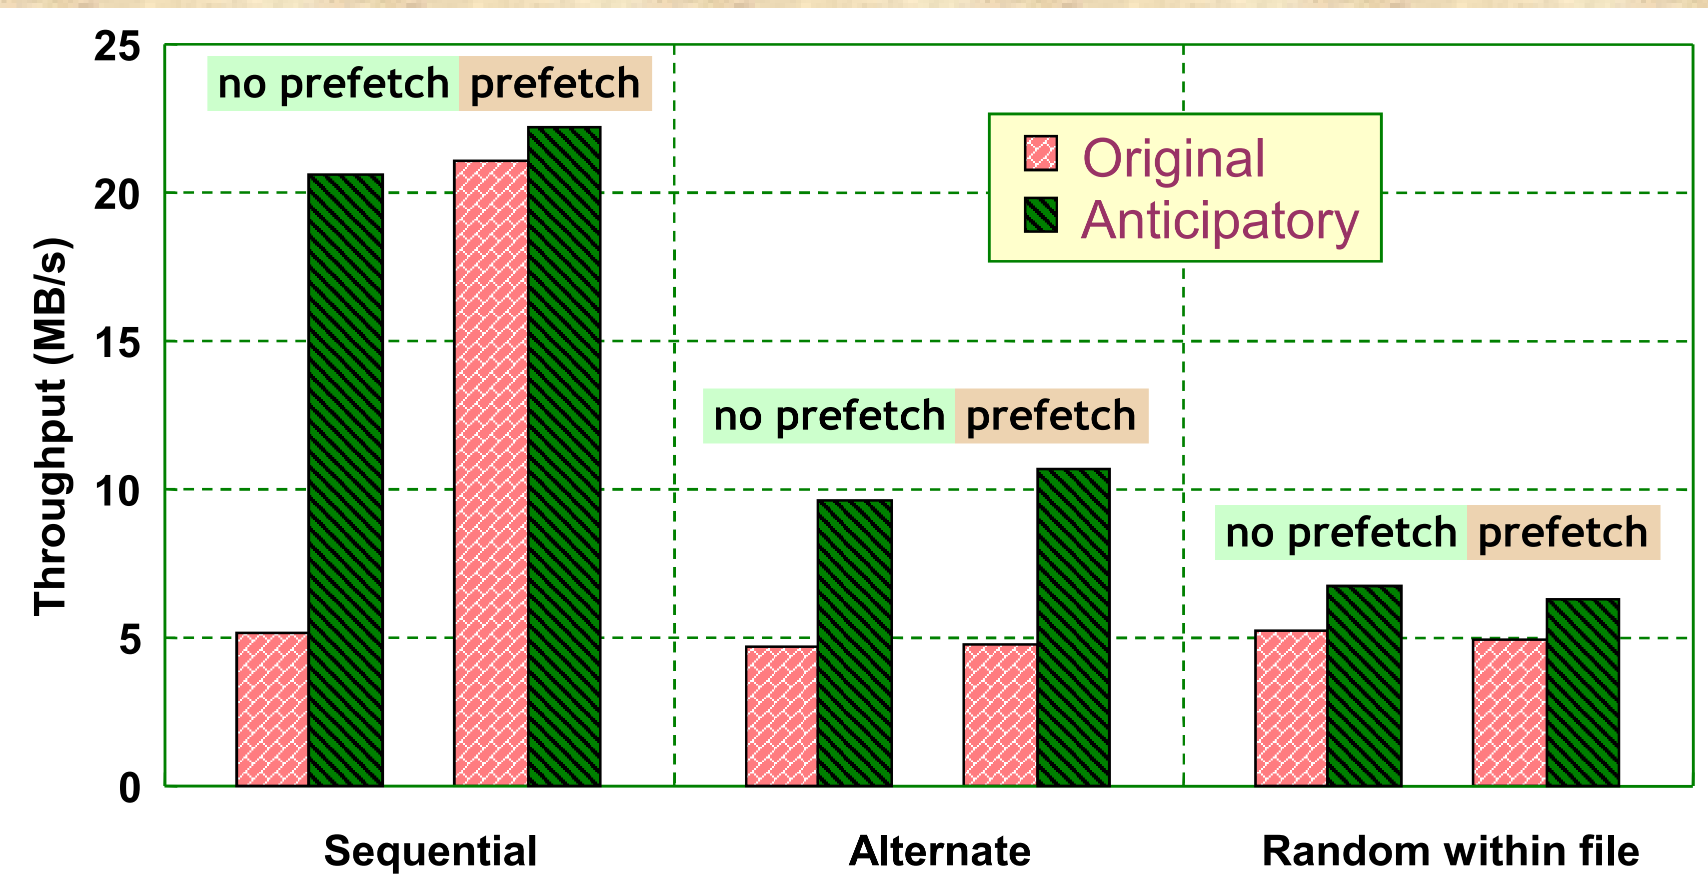
Side-effect:
avoids deceptive idleness!

- Application-driven
- Kernel-driven

Experiments

- FreeBSD-4.3 patch + kernel module (1500 lines of C code)
- 7200 rpm IDE disk (IBM Deskstar)
- Also in the paper:
  15000 rpm SCSI disk (Seagate Cheetah)

Microbenchmark



Real workloads

What's the impact on real applications and benchmarks?

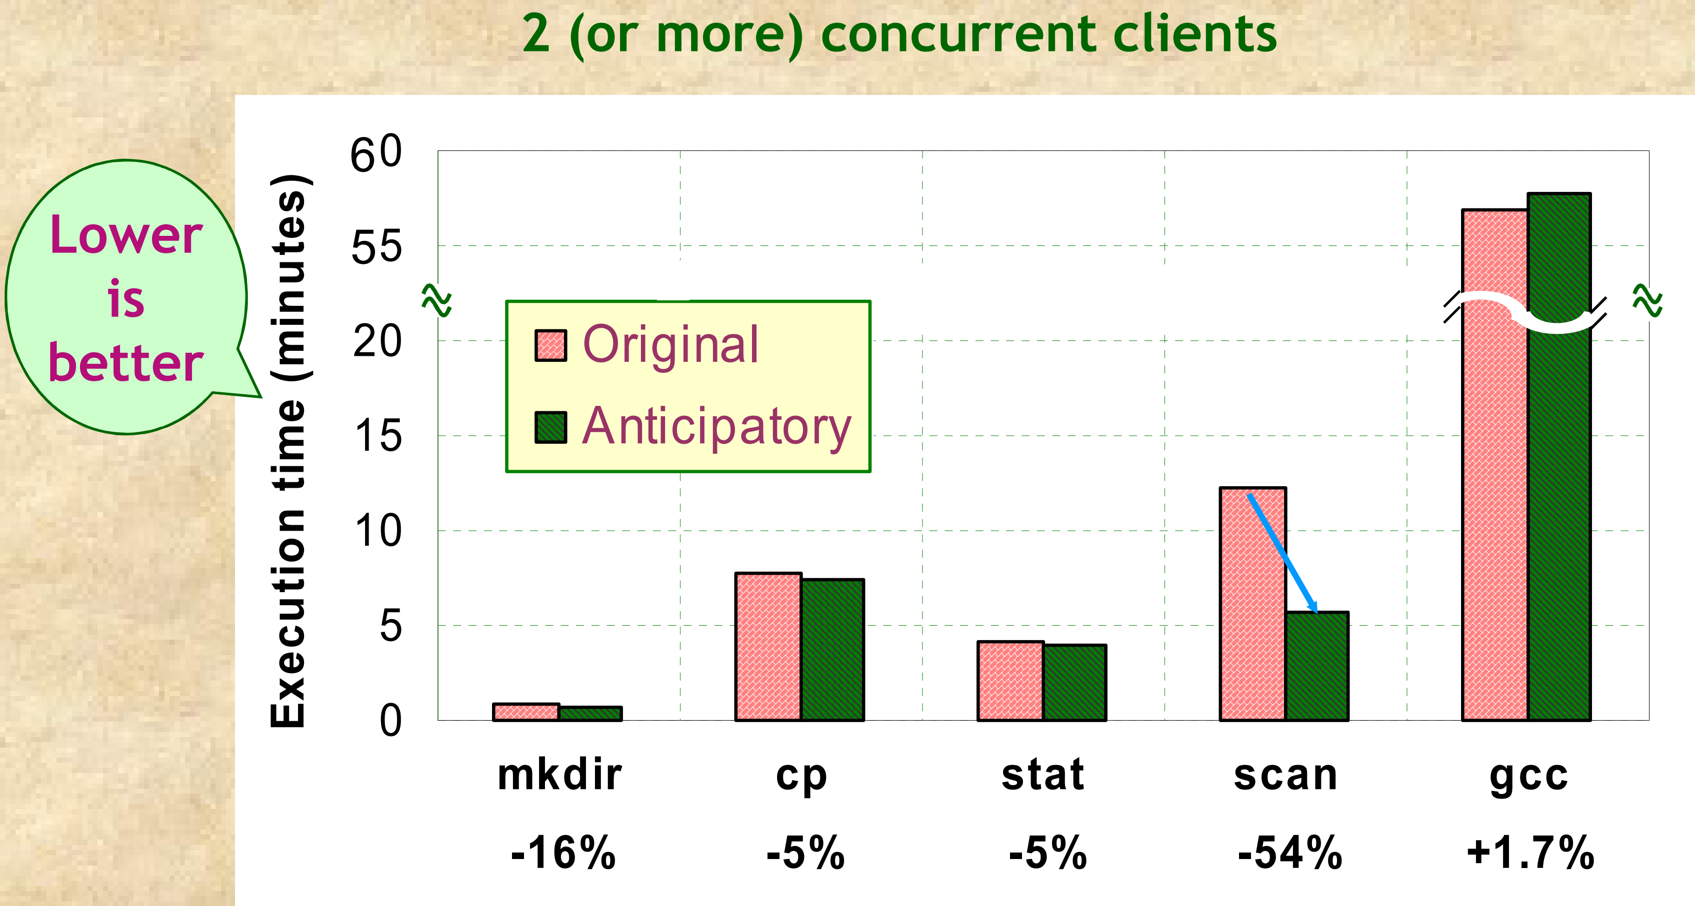
Andrew benchmark

Apache web server
(large working set)

Database benchmark

- Disk-intensive
- Prefetching enabled

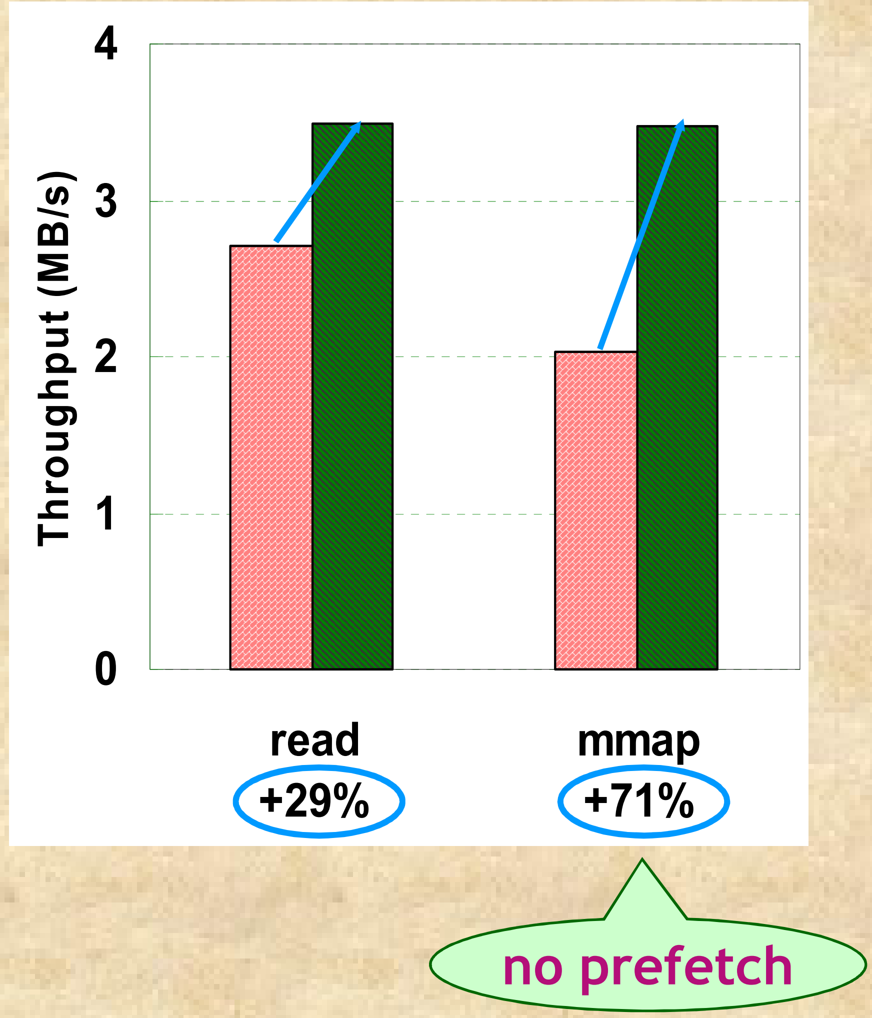
Andrew filesystem benchmark



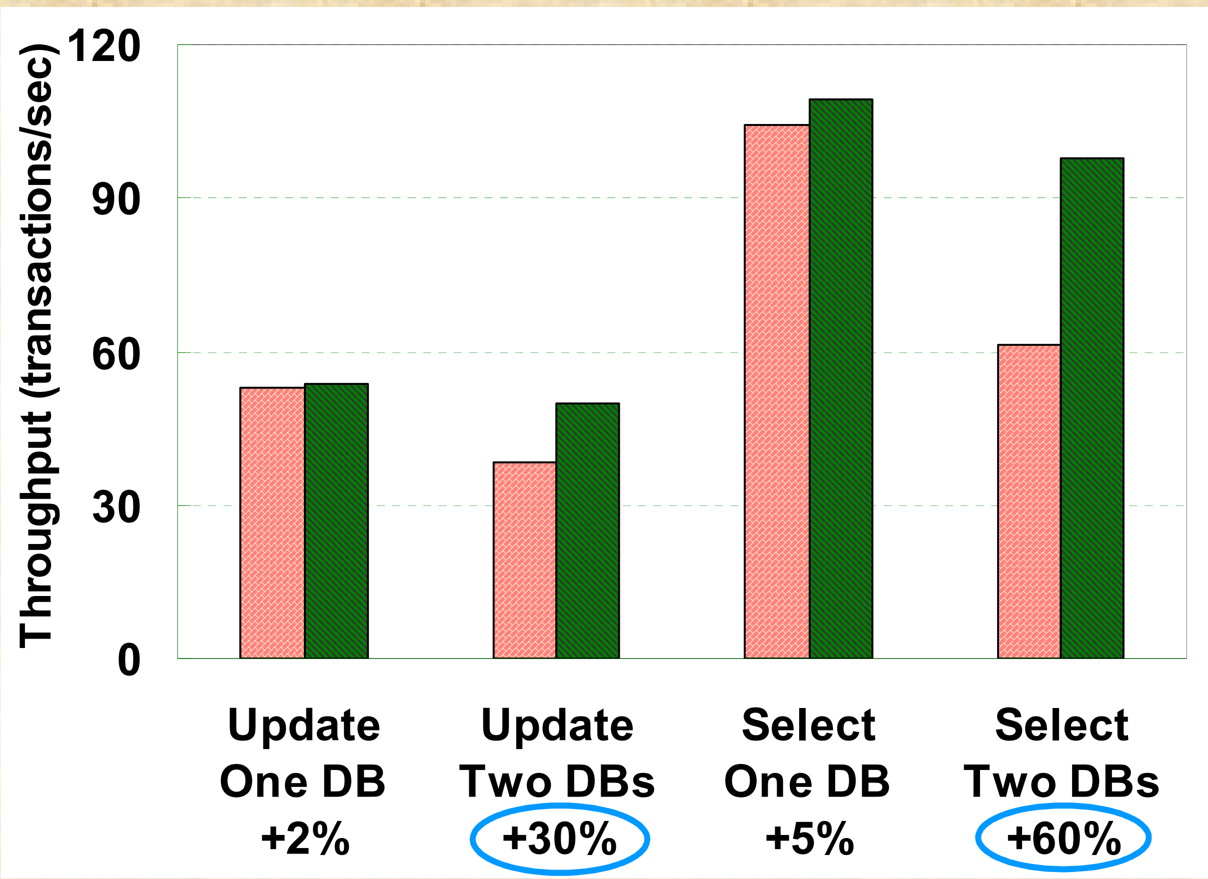
Overall 8% performance improvement

Apache web server

- CS.Berkeley trace
- Large working set
- 48 web clients

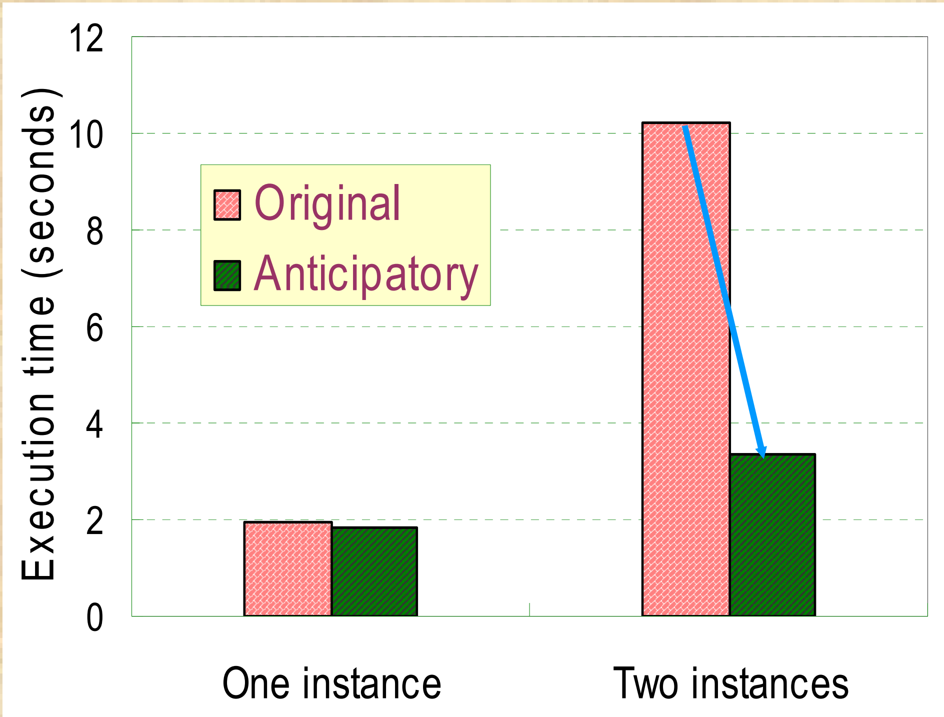


Database benchmark



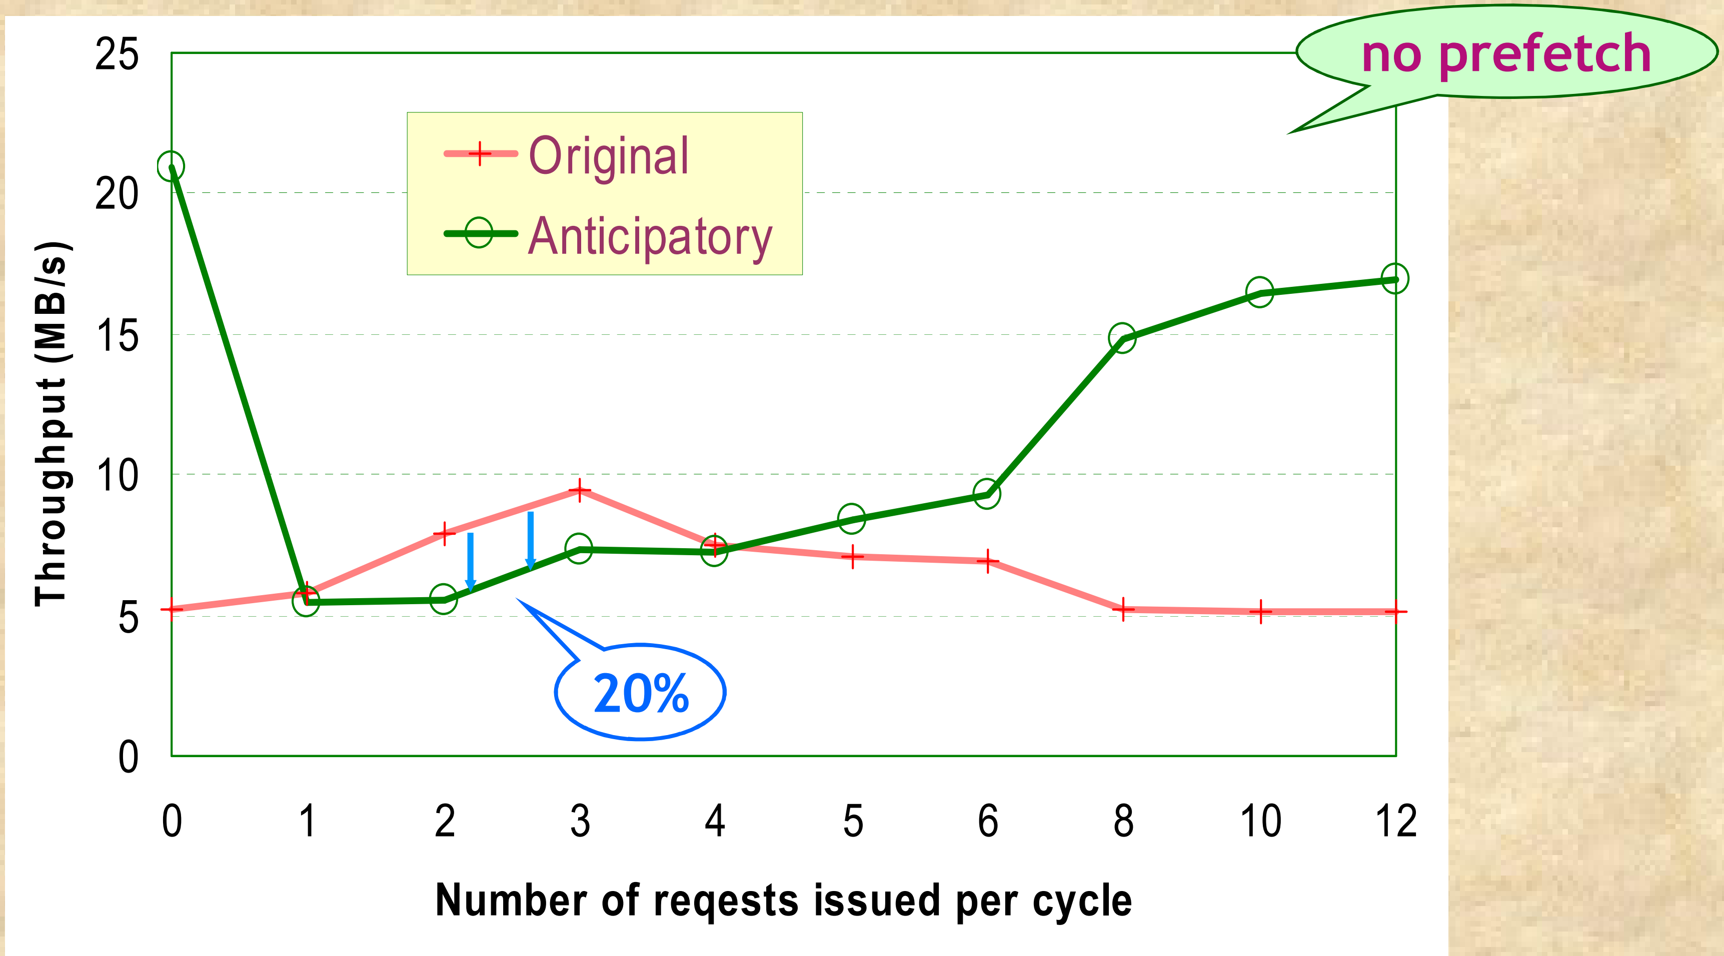
- MySQL DB
- Two clients
- One or two databases on same disk

GnuLD

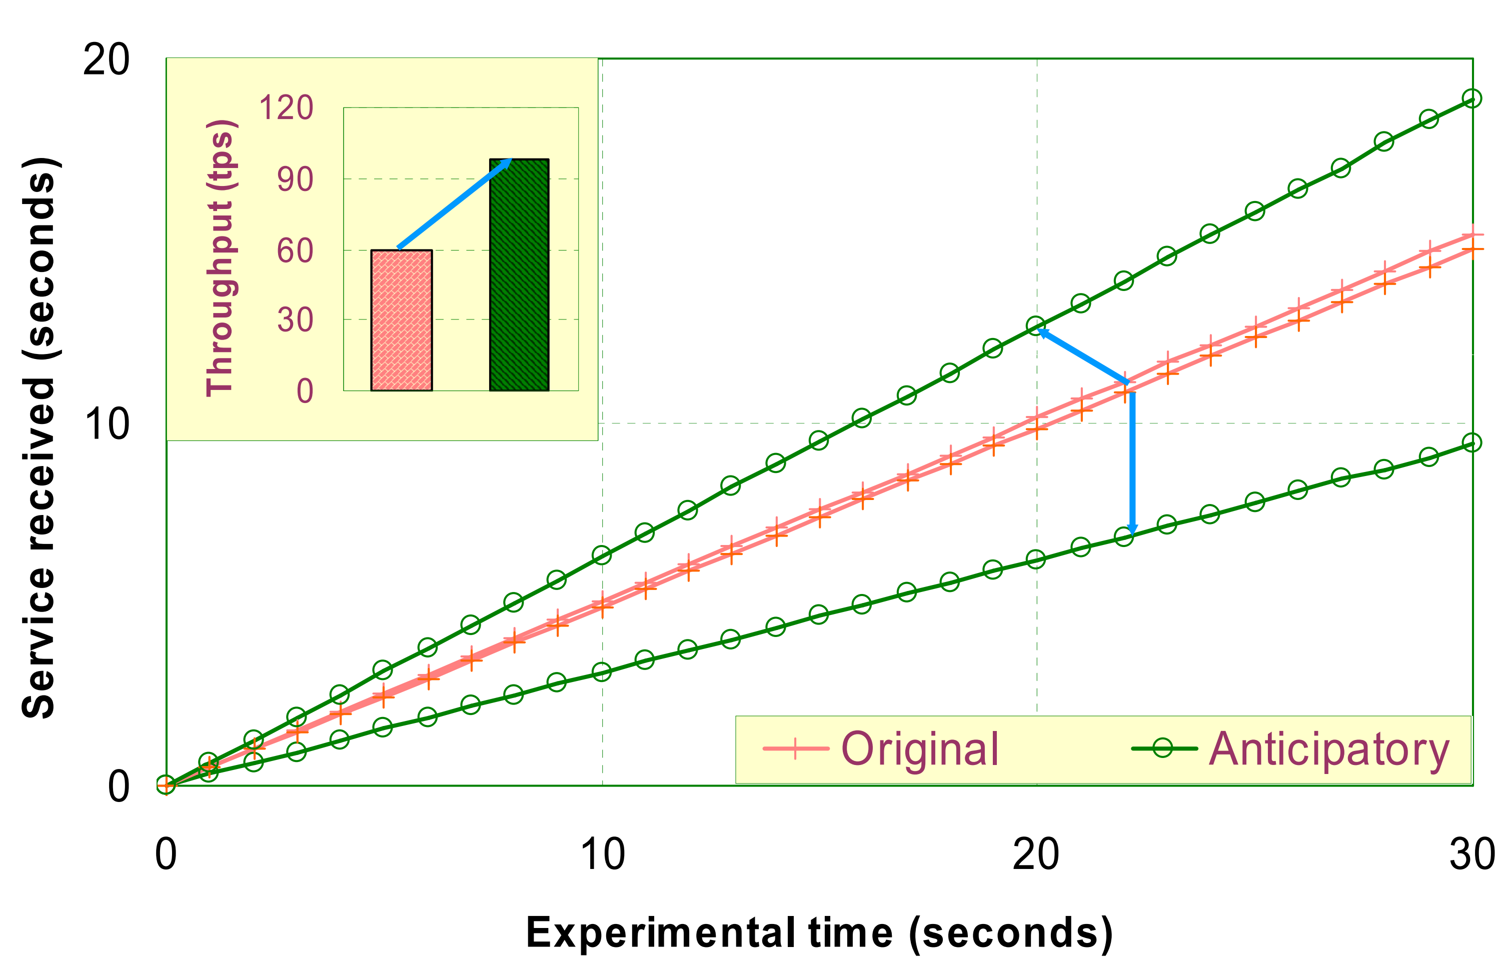


Concurrent: 68% execution time reduction

Intelligent adversary



Proportional scheduler



Database benchmark: two databases, select queries

Conclusion

Anticipatory scheduling:

- overcomes deceptive idleness
- achieves significant performance improvement on real applications
- achieves desired proportions
- and is easy to implement!
