Scheduling

Learning Outcomes

- Understand the role of the scheduler, and how its behaviour influences the performance of the system.

- Know the difference between I/O-bound and CPU-bound tasks, and how they relate to scheduling.

- Understand typical interactive and real time scheduling approaches.

What is Scheduling?

- – On a multi-programmed system
  - We may have more than one *Ready* process
- – On a batch system
  - We may have many jobs waiting to be run
- – On a multi-user system
  - We may have many users concurrently using the system

- The **scheduler** decides who to run next.
  - – The process of choosing is called *scheduling.*

THE UNIVERSITY OF
NEW SOUTH WALES

Is scheduling important?

- It is not in certain scenarios
  - If you have no choice
    - Early systems
      - Usually batching
      - Scheduling algorithm simple
        - » Run next on tape or next on punch tape
  - Only one thing to run
    - Simple PCs
      - Only ran a word processor, etc….
    - Simple Embedded Systems
      - TV remote control, washing machine, etc….

THE UNIVERSITY OF
NEW SOUTH WALES

Is scheduling important?

- It is in most realistic scenarios
  - Multitasking/Multi-user System
    - Example
      - Email daemon takes 2 seconds to process an email
      - User clicks button on application.
    - Scenario 1
      - Run daemon, then application
        - » System appears really sluggish to the user
    - Scenario 2
      - Run application, then daemon
        - » Application appears really responsive, small email delay is unnoticed

- Scheduling decisions can have a dramatic effect on the perceived performance of the system
 - Can also affect correctness of a system with deadlines

THE UNIVERSITY OF
NEW SOUTH WALES

5

Application Behaviour
- Bursts of CPU usage alternate with periods of I/O wait

Application Behaviour

(a) Long CPU burst — Waiting for I/O

(b) Short CPU burst

Time

a) CPU-Bound process
   - Spends most of its computing
   - Time to completion largely determined by received CPU time

Application Behaviour

(a)

Long CPU burst

Waiting for I/O

Short CPU burst

(b)

Time

b) I/O-Bound process

- – Spend most of its time waiting for I/O to complete
  - • Small bursts of CPU to process I/O and request next I/O
- – Time to completion largely determined by I/O request time

Observations

(a) Long CPU burst · Waiting for I/O

(b) Short CPU burst · Time

- Generally, technology is increasing CPU speed much faster than I/O speed
  - $\Rightarrow$ CPU bursts becoming shorter, I/O waiting is relatively constant
 - $\Rightarrow$ Processes are becoming more I/O bound

Observations

- We need a mix of CPU-bound and I/O-bound processes to keep both CPU and I/O systems busy
- Process can go from CPU- to I/O-bound (or vice versa) in different phases of execution

Observations

- Choosing to run an I/O-bound process delays a CPU-bound process by very little
- Choosing to run a CPU-bound process prior to an I/O-bound process delays the next I/O request significantly
    - No overlap of I/O waiting with computation
    - Results in device (disk) not as busy as possible
- ⇒ Generally, favour I/O-bound processes over CPU-bound processes

When is scheduling performed?

- A new process
  - Run the parent or the child?
- A process exits
  - Who runs next?
- A process waits for I/O
  - Who runs next?
- A process blocks on a lock
  - Who runs next? The lock holder?
- An I/O interrupt occurs
  - Who do we resume, the interrupted process or the process that was waiting?
- On a timer interrupt? (See next slide)

- Generally, a scheduling decision is required when a process (or thread) can no longer continue, or when an activity results in more than one ready process.

THE UNIVERSITY OF
NEW SOUTH WALES

Preemptive versus Non-preemptive Scheduling

- ## Non-preemptive
  - Once a thread is in the *running* state, it continues until it completes, blocks on I/O, or voluntarily yields the CPU
  - A single process can monopolised the entire system

- ## Preemptive Scheduling
  - Current thread can be interrupted by OS and moved to *ready* state.
  - Usually after a timer interrupt and process has exceeded its maximum run time
    - Can also be as a result of higher priority process that has become *ready* (after I/O interrupt).
  - Ensures fairer service as single thread can't monopolise the system
    - Requires a timer interrupt

13

Categories of Scheduling Algorithms

- The choice of scheduling algorithm depends on the goals of the application (or the operating system)
  - No one algorithm suits all environments

- We can roughly categorise scheduling algorithms as follows
  - Batch Systems
    - No users directly waiting, can optimise for overall machine performance
  - Interactive Systems
    - Users directly waiting for their results, can optimise for users perceived performance
  - Realtime Systems
    - Jobs have deadlines, must schedule such that all jobs (mostly) meet their deadlines.

THE UNIVERSITY OF
NEW SOUTH WALES

Goals of Scheduling Algorithms

- ## All Algorithms
  - ### Fairness
    - Give each process a *fair* share of the CPU
  - ### Policy Enforcement
    - What ever policy chosen, the scheduler should ensure it is carried out
  - ### Balance/Efficiency
    - Try to keep all parts of the system busy

THE UNIVERSITY OF
NEW SOUTH WALES

Goals of Scheduling Algorithms

- **Interactive Algorithms**
  - Minimise *response time*
    - Response time is the time difference between issuing a command and getting the result
      - E.g selecting a menu, and getting the result of that selection
    - Response time is important to the user's perception of the performance of the system.
  - Provide *Proportionality*
    - Proportionality is the user expectation that short jobs will have a short response time, and long jobs can have a long response time.
    - Generally, favour short jobs

THE UNIVERSITY OF
NEW SOUTH WALES

Goals of Scheduling Algorithms

- ## Real-time Algorithms
  - ### Must meet deadlines
    - Each job/task has a deadline.
    - A missed deadline can result in data loss or catastrophic failure
      - Aircraft control system missed deadline to apply brakes
  - ### Provide Predictability
    - For some apps, an occasional missed deadline is okay
      - E.g. DVD decoder
    - Predictable behaviour allows smooth DVD decoding with only rare skips

Interactive Scheduling

Round Robin Scheduling

- Each process is given a *timeslice* to run in
- When the timeslice expires, the next process preempts the current process, and runs for its timeslice, and so on
  - The preempted process is placed at the end of the queue
- Implemented with
  - A ready queue
  - A regular timer interrupt

THE UNIVERSITY OF
NEW SOUTH WALES

Example
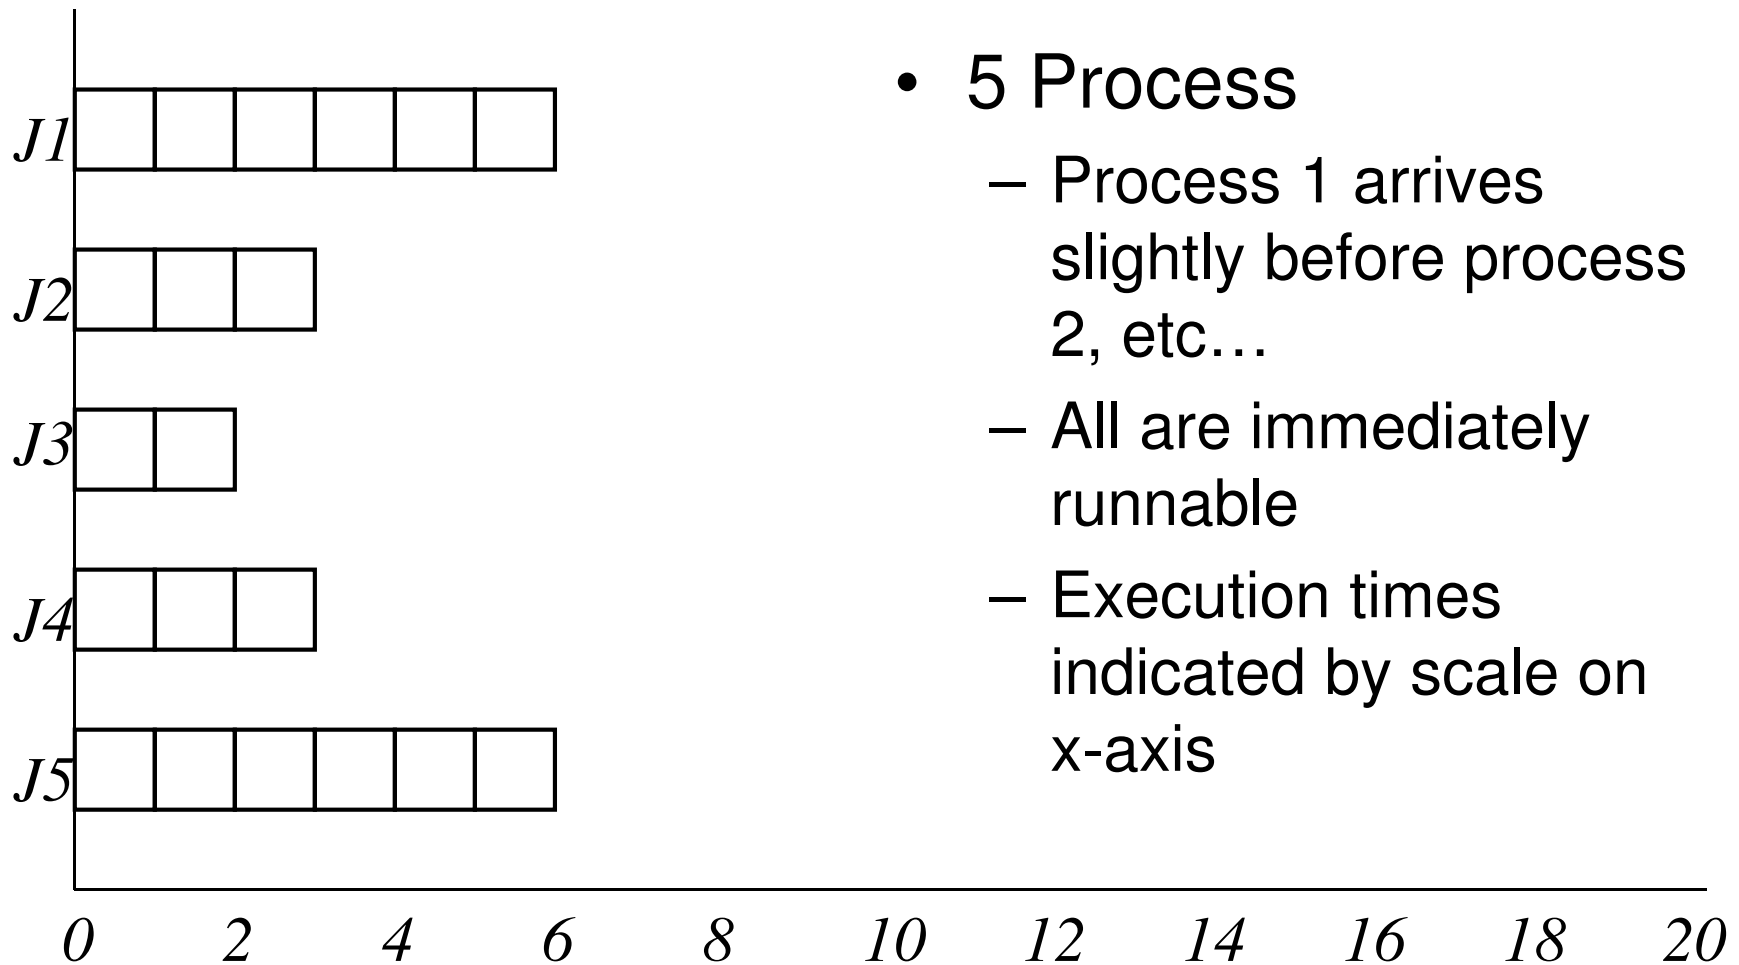

- 5 Process
  - Process 1 arrives slightly before process 2, etc…
  - All are immediately runnable
  - Execution times indicated by scale on x-axis

20

Round Robin Schedule

Timeslice = 1 unit

THE UNIVERSITY OF
NEW SOUTH WALES

Round Robin Schedule

Timeslice = 3 units

THE UNIVERSITY OF
NEW SOUTH WALES
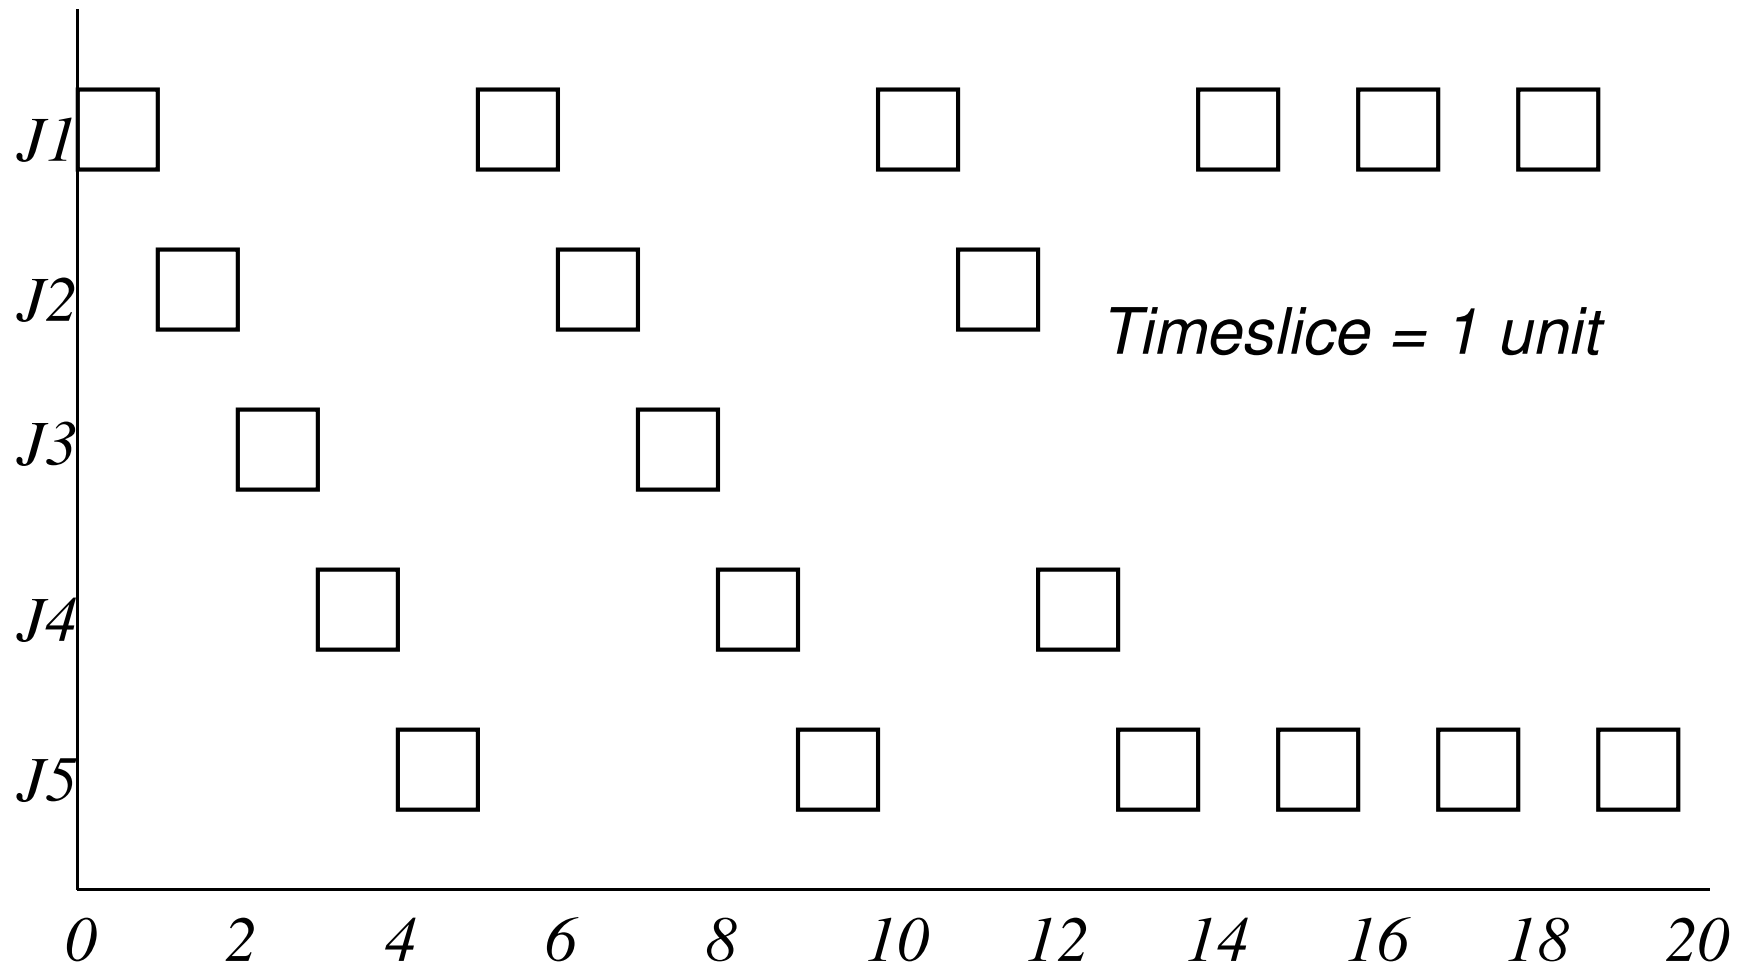

Round Robin

- Pros
  - Fair, easy to implement
- Con
  - Assumes everybody is equal
- Issue: What should the timeslice be?
  - Too short
    - Waste a lot of time switching between processes
    - Example: timeslice of 4ms with 1 ms context switch = 20% round robin overhead
  - Too long
    - System is not responsive
    - Example: timeslice of 100ms
      - If 10 people hit "enter" key simultaneously, the last guy to run will only see progress after 1 second.
    - Degenerates into FCFS if timeslice longer than burst length

Priorities

- Each Process (or thread) is associated with a priority

- Provides basic mechanism to influence a scheduler decision:

  - Scheduler will always chooses a thread of higher priority over lower priority

- Priorities can be defined internally or externally

  - Internal: e.g. I/O bound or CPU bound

  - External: e.g. based on importance to the user

THE UNIVERSITY OF
NEW SOUTH WALES
Example

- 5 Jobs
  - Job number equals priority
  - Priority 1 > priority 5
  - Release and execution times as shown
- Priority-driven preemptively scheduled

Priorities

- Usually implemented by multiple priority queues, with round robin on each queue
- Con
  - Low priorities can starve
    - Need to adapt priorities periodically
      - Based on ageing or execution history

Traditional UNIX Scheduler

- Two-level scheduler
  - High-level scheduler schedules processes between memory and disk
  - Low-level scheduler is CPU scheduler
    - Based on a multi-level queue structure with round robin at each level

THE UNIVERSITY OF
NEW SOUTH WALES

48
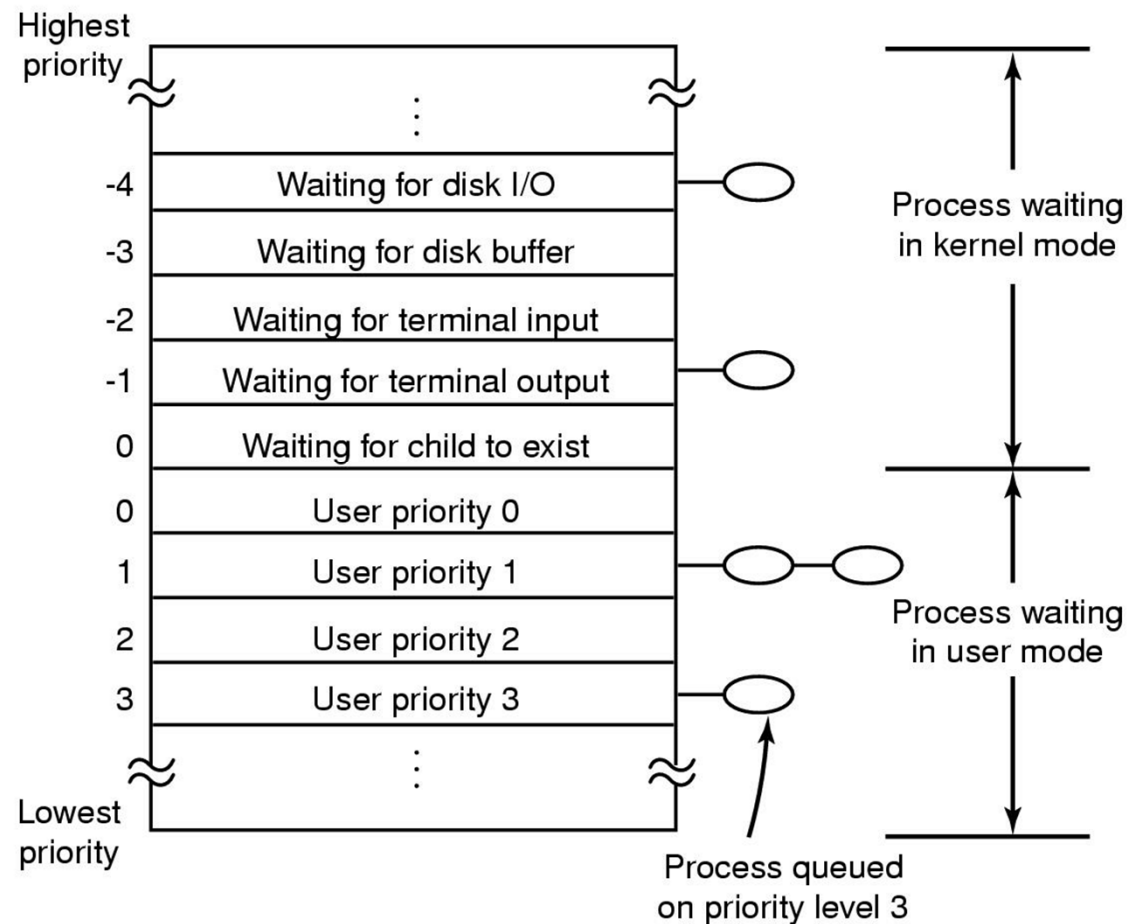

Traditional UNIX Scheduler

- The highest priority (lower number) is scheduled

- Priorities are re-calculated once per second, and re-inserted in appropriate queue
  - Avoid starvation of low priority threads
  - Penalise CPU-bound threads

THE UNIVERSITY OF
NEW SOUTH WALES

49
Traditional UNIX Scheduler

- *Priority = CPU_usage +nice +base*
  - *CPU_usage* = number of clock ticks
    - Decays over time to avoid permanently penalising the process
  - *Nice* is a value given to the process by a user to permanently boost or reduce its priority
    - Reduce priority of background jobs
  - *Base* is a set of hardwired, negative values used to boost priority of I/O bound system activities
    - Swapper, disk I/O, Character I/O

Highest priority

-4	Waiting for disk I/O
-3	Waiting for disk buffer
-2	Waiting for terminal input
-1	Waiting for terminal output
0	Waiting for child to exist
0	User priority 0
1	User priority 1
2	User priority 2
3	User priority 3

Lowest priority

Process waiting in kernel mode

Process waiting in user mode

Process queued on priority level 3

50

Real-time Scheduling

THE UNIVERSITY OF
NEW SOUTH WALES
Real Time Scheduling

- Correctness of the system may depend not only on the logical result of the computation but also **on the time when** these results are produced, e.g.
  - Tasks attempt to control events or to react to events that take place in the outside world
  - These external events occur in *real time* and processing must be able to keep up
  - Processing must happen in a timely fashion,
    - neither too late, nor too early

Real Time System (RTS)

- RTS accepts an activity *A* and guarantees its requested (timely) behaviour *B* if and only if
  - RTS finds a *schedule*
    - that includes all already accepted activities *Ai* and the new activity *A*,
    - that guarantees all requested timely behaviour *Bi* and *B*, and
    - that can be enforced by the RTS.

- Otherwise, RT system rejects the new activity *A.*

Typical Real Time Systems

- Control of laboratory experiments
- Robotics
- (Air) Traffic control
- Controlling Cars / Trains/ Planes
- Telecommunications
- Medical support (Remote Surgery, Emergency room)
- Multi-Media

- Remark: Some applications may have only **soft-real time** requirements, but some have really **hard real-time** requirements

Hard-Real Time Systems

- Requirements:
  - **Must *always* meet all deadlines** (time guarantees)
  - You have to guarantee that in any situation these applications are done in time, otherwise dangerous things may happen

Examples:

1. If the landing of a fly-by-wire jet cannot react to sudden side-winds within some milliseconds, an accident might occur.
2. An airbag system or the ABS has to react within milliseconds

Soft-Real Time Systems

Requirements:

Must *mostly* meet all deadlines, e.g. 99.9% of cases

Examples:

1. Multi-media: 100 frames per day might be dropped (late)

2. Car navigation: 5 late announcements per week are acceptable

3. Washing machine: washing 10 sec over time might occur once in 10 runs, 50 sec once in 100 runs.
THE UNIVERSITY OF
NEW SOUTH WALES

Predictability, not Speed

- Real time systems are NOT necessarily fast

- Real time systems can be slow, as long as they are predictably so.
  - It does not matter how fast they are, as long as they meet their deadlines.

Properties of Real-Time Tasks

- To schedule a real time task, its properties must be known *a priori*

- The most relevant properties are
  - Arrival time (or release time) a_i
  - Maximum execution time (service time)
  - Deadline d_i

service time   slack-time, laxity

Ti

ai:
earliest
start time

si:
effective
start time

ei:
effective
termination time

di:
latest
termination time
deadline

58

Categories of Real time tasks

- Periodic
  - Each task is repeated at a regular interval
  - Max execution time is the same each period
  - Arrival time is usually the start of the period
  - Deadline is usually the end
- Aperiodic (and sporadic)
  - Each task can arrive at any time

Real-time scheduling approaches

- Static table-driven scheduling
  - Given a set of tasks and their properties, a schedule (table) is precomputed offline.
    - Used for periodic task set
    - Requires entire schedule to be recomputed if we need to change the task set
- Static priority-driven scheduling
  - Given a set of tasks and their properties, each task is assigned a fixed priority
  - A preemptive priority-driven scheduler used in conjunction with the assigned priorities
    - Used for periodic task sets

Real-time scheduling approaches

- ## Dynamic scheduling
  - Task arrives prior to execution
  - The scheduler determines whether the new task can be *admitted*
    - Can all other admitted tasks and the new task meet their deadlines?
      - If no, reject the new task
  - Can handle both *periodic* and *aperiodic* tasks

Scheduling in Real-Time Systems

- We will only consider periodic systems

Schedulable real-time system

- Given
  - *m* periodic events
  - event *i* occurs within period P_i and requires C_i seconds
- Then the load can only be handled if

$$\sum_{i=1}^{m} \frac{C_i}{P_i} \leq 1$$

THE UNIVERSITY OF
NEW SOUTH WALES

Two Typical Real-time Scheduling Algorithms

- Rate Monotonic Scheduling
  - Static Priority priority-driven scheduling
  - Priorities are assigned based on the period of each task
    - The shorter the period, the higher the priority

- Earliest Deadline First Scheduling
  - The task with the earliest deadline is chosen next

A Scheduling Example
- Three periodic Tasks
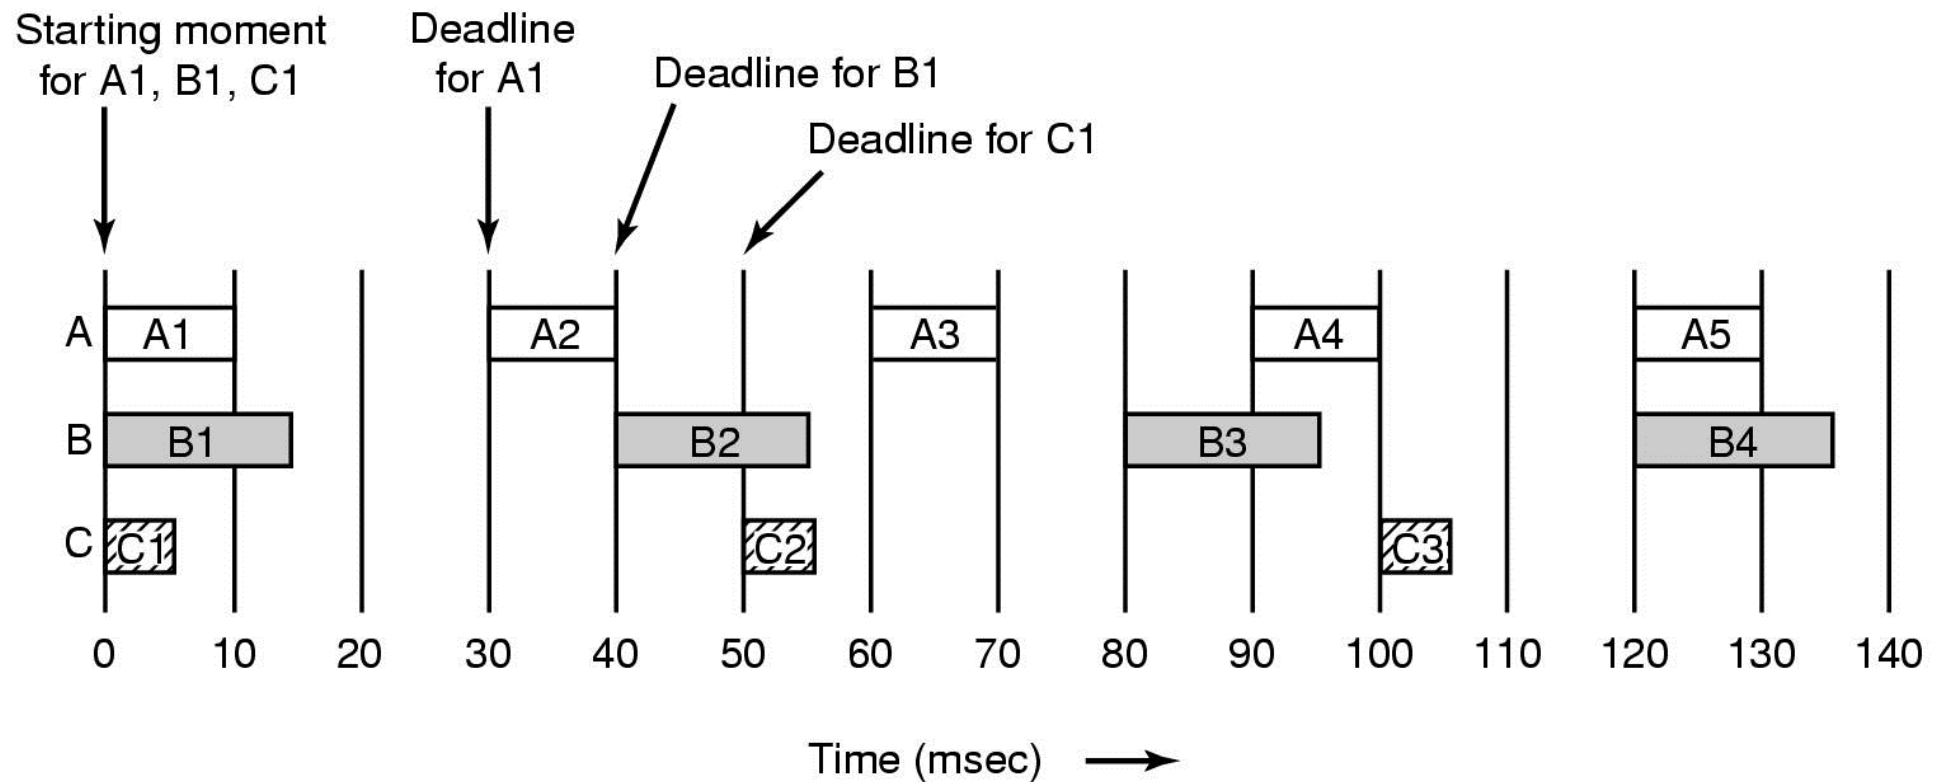

Is the Example Schedulable

$$\sum_{i=1}^{m} \frac{C_i}{P_i} \leq 1$$

$$\frac{10}{30} + \frac{15}{40} + \frac{5}{50} = 0.808$$
- YES

Two Schedules: RMS and EDF

Time (msec) →

THE UNIVERSITY OF
NEW SOUTH WALES

Two Schedules: RMS and EDF

Time (msec) →
THE UNIVERSITY OF NEW SOUTH WALES

Let's Modify the Example Slightly

- Increase A's CPU requirement to 15 msec
- The system is still schedulable

$$\frac{15}{30} + \frac{15}{40} + \frac{5}{50} = 0.975$$

THE UNIVERSITY OF
NEW SOUTH WALES

RMS and EDF

Time (msec) →

RMS and EDF

RMS failed, why?

- It has been proven that RMS is only guaranteed to work if the CPU utilisation is not too high

  - For three tasks, CPU utilisation must be less than 0.780

    - We were lucky with our original example

$$\sum_{i=1}^{m} \frac{C_i}{P_i} \leq m(2^{1/m} - 1)$$

THE UNIVERSITY OF
NEW SOUTH WALES

EDF

- EDF always works for any schedulable set of tasks, i.e. up to 100% CPU utilisation

- Summary
  - If CPU utilisation is low (usual case, due to safety factor in estimating execution times)
    - Can use RMS which is simple and easy to implement
  - If CPU utilisation is high
    - Must use EDF

THE UNIVERSITY OF
NEW SOUTH WALES
